

Antenna Briefs #4 -- Interstellar Communication and SETI (Revised)

Slides downloaded from: <https://ecefiles.org/rf-design/>

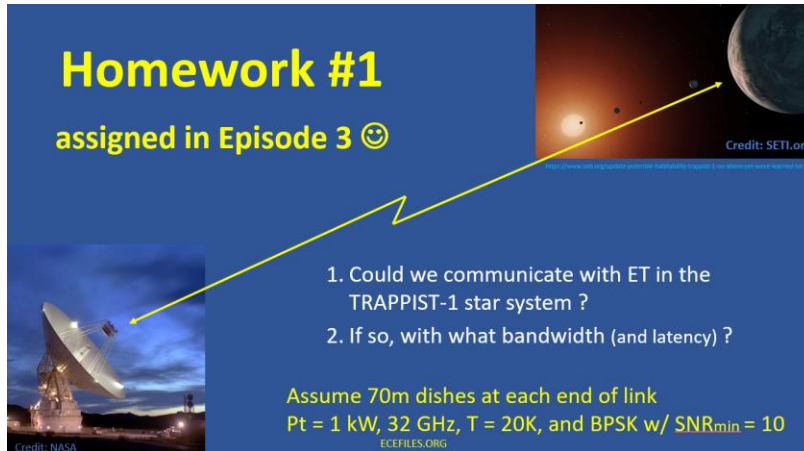

Companion video at: <https://www.youtube.com/watch?v=fuOVn2YgWRA>

This material is [provided by ecefiles.org](https://ecefiles.org) for educational use only.

This episode looks at communicating across distances of several light-years, and at the big antennas and very large power levels needed. In this revised episode, we start with an errata (list of changes) to the previous Episode 4 video. We then proceed, as before, to the solution to the "homework" problem assigned in episode 3 and apply the results to the Search for Extraterrestrial Intelligence (SETI). The goal is to determine the power levels that must be used, the antenna's needed, and the narrow bandwidths that may be required by "ET" to 'talk' to us, very slowly ... ;-)

Homework #1

assigned in Episode 3 😊

1. Could we communicate with ET in the TRAPPIST-1 star system ?
2. If so, with what bandwidth (and latency) ?

Assume 70m dishes at each end of link
Pt = 1 kW, 32 GHz, T = 20K, and BPSK w/ SNR_{min} = 10

Credit: NASA Credit: SETI.org ECEFILES.ORG

Things to Ponder ...

- At 1.2 MW with 70m dish at 1.42 GHz, ET needs to point at us with accuracy of 0.15°
Or, do an omnidirectional broadcast with Pt = EIRP = (1 kW)(5.5E8) = **500 GW** !
- They don't know when we're listening - so they need to transmit for years/decades
- Why would they do all of this ?
(Maybe they have emotional intelligence too, and want to be helpful/nice...)
- Other possibilities

Antenna Briefs #4A

Interstellar Comm and SETI (Revised)

Homework #1

assigned in Episode 3 😊

Credit: SETI.org

<https://www.seti.org/update-potential-habitability-trappist-1-no-aliens-yet-weve-learned-lot>

1. Could we communicate with ET in the TRAPPIST-1 star system ?
2. If so, with what bandwidth (and latency) ?

Assume 70m dishes at each end of link

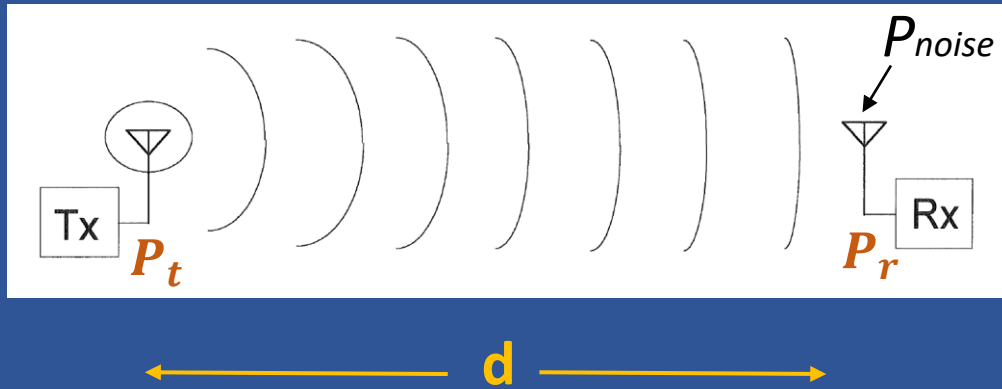

$P_t = 1 \text{ kW}$, 32 GHz, $T = 20\text{K}$, and BPSK w/ $\text{SNR}_{\min} = 10$

ECEFILES.ORG

Credit: NASA

Key Equations from Episode 3

$$P_{density} = \frac{P_t G_t}{4\pi d^2}$$

$$P_r = P_{density} A_{eff}$$

$$G_t = \frac{4\pi A_{eff}}{\lambda^2}$$

$$A_{eff} \approx \pi \left(\frac{dia}{2}\right)^2$$

$$P_r = P_t G_t \frac{1}{4\pi d^2} A_{eff}$$

Make this big enough:
i.e. $P_r > P_{noise}$, where

$$P_{noise} = k T B$$

$k=1.38E-23$ W/Hz.K,
T is temperature in Kelvin
B is bandwidth in Hz

(Revised) Homework Solution

$$\text{Need: } P_r = P_t \frac{G_t}{4\pi d^2} A_{eff} > (kTB) SNR_{min}$$

Given:

$P_t = 1000 \text{ W}$

Frequency 32 GHz

Earth-Trappist-1 distance: 39.5LY = 3.7E17 m

Transmit dish diameter: 70 m

Receiver dish diameter: 70 m

$T = 20\text{K}$, $SNR_{min} = 10$

Try: bandwidth = 1 Hz ...

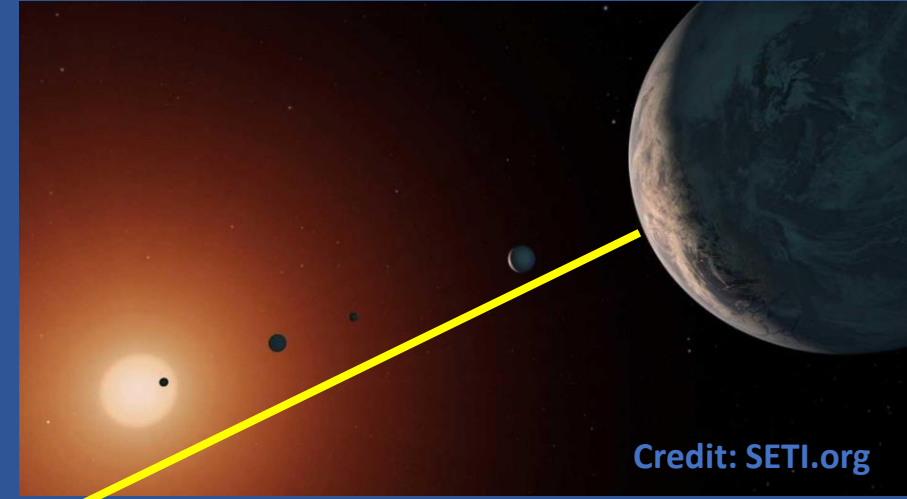

Then:

$$P_r = 1.2\text{E-}21 \text{ (-179 dBm)}$$

$$kTB = 2.8\text{E-}22 \text{ W (-186 dBm)}$$

$$SNR = 4.3 \text{ (+6 dB)}$$

ECEFILES.ORG

Credit: SETI.org

<https://www.seti.org/update-potential-habitability-trappist-1-no-aliens-yet-weve-learned-lot>

Some (approx.) intermediate values:

$$\lambda = \frac{c}{f} = 0.0094 \text{ m}$$

$$G_t = 5.5\text{E}8$$

$$A_{eff} = 3800 \text{ m}^2$$

229 trillion Miles

Scaling to get the answer...

Recall SNR needs to be 10 or higher.

So we need to drop bandwidth by a factor of $10/4.3 = 2.3$, to **0.4Hz**

Latency is 2×39.5 years ☹️

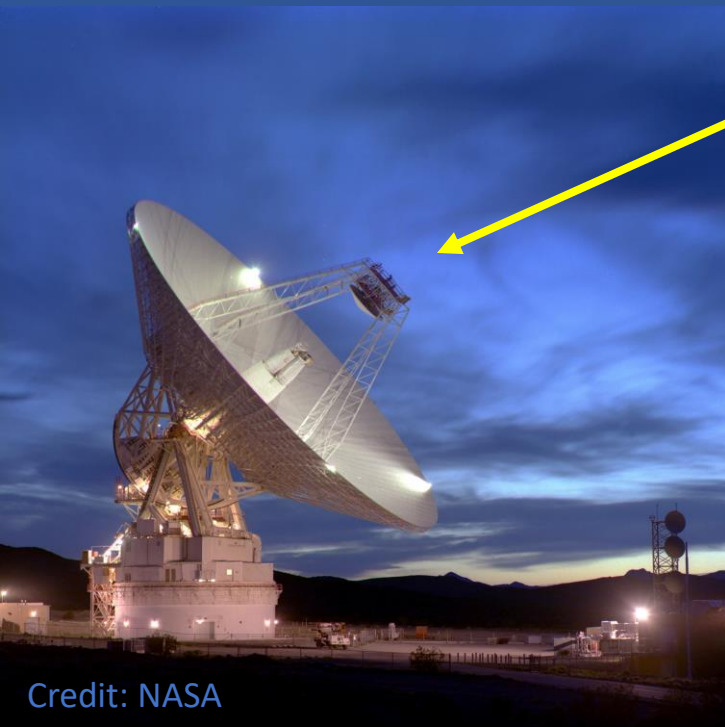

Credit: NASA

Implications for SETI

Credit: SETI.org

<https://www.seti.org/update-potential-habitability-trappist-1-no-aliens-yet-weve-learned-lot>

- No “conversations”, at least within a human lifetime
- A bandwidth of 0.4 Hz is a little hard to achieve at 32 GHz (requires oscillator stability of $1E-11$)
- 32 GHz is not the ‘right’ frequency for SETI anyway.

So How Can ET Reach Us ?

We Need:
$$P_r = P_t G_t \frac{1}{4 \pi d^2} A_{eff} > (k T B) SNR_{min}$$

Recall homework result:

- SNR was 4.3 at B=1Hz with 70m dishes at each end, but we wanted SNR ≥ 10

$P_t G_t$ used by ET needs to increase by...

- 2.3x if we use 1 Hz bandwidth in our search
- 500x more to use the 1420 MHz magic frequency

ET's Options:

- Increase P_t from 1 kW to **1.2 MW**, or
- Increase transmit antenna from 70m to **2.3 km diameter** (and point it really well !), or
- Use some combination thereof, or
- Wait till we make our antenna a lot bigger (and/or use much lower bandwidth...)

NOTE:

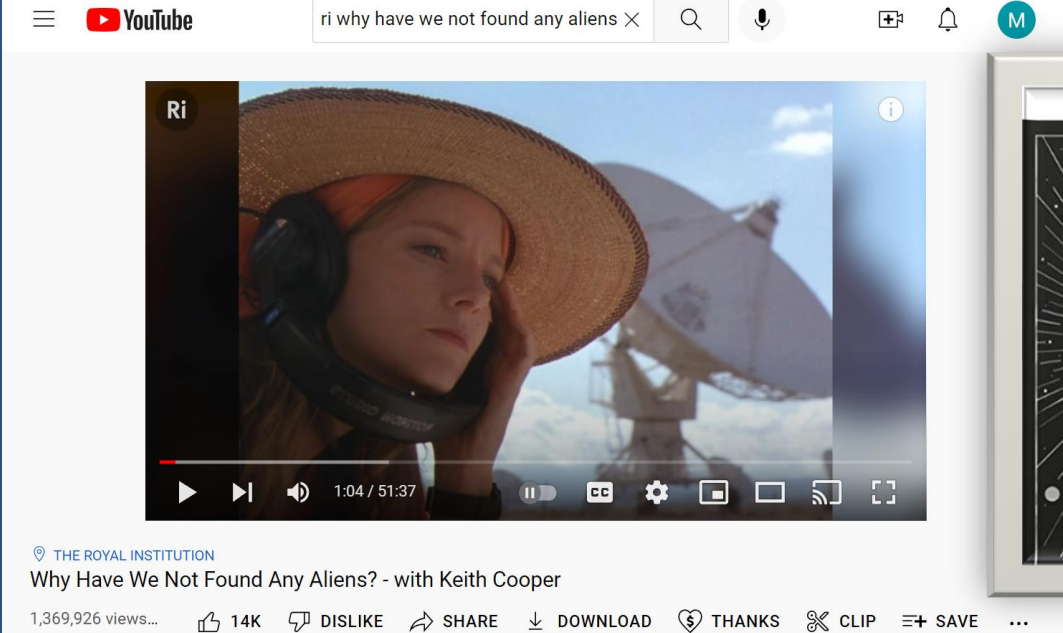

- This is for Trappist-1 at 39.5 LY
- To reach to around 400 LY (for more candidate stars), we need another factor of 100x in $P_t G_t$ or A_{eff}

Things to Ponder ...

- At 1.2 MW with 70m dish at 1.42 GHz, ET needs to point at us with accuracy of 0.15°
Or, do an omnidirectional broadcast with $P_t = \text{EIRP} = (1 \text{ kW})(5.5\text{E}8) = 500 \text{ GW} !$
- They don't know when we're listening - so they need to transmit for years/decades
- Why would they do all of this ?
(Maybe they have emotional intelligence too, and want to be helpful/nice...)
- Other possibilities

Future “Antenna Briefs” Episodes

Back to Earth in Episode 5:

Electric (E) and magnetic (B) fields

Power and impedance

Far-field pattern calculation

Antenna simulation

What “are” E, B and EM fields ?

Additional episodes

- Antenna counterpoise, baluns, and chokes
- Reflection of E and H fields
- Design of some basic antenna types
- Phase, superposition, and beamforming...

Thanks for Watching

- Traditionally the Hydrogen line frequency of 1.42 GHz is targeted (assumed most likely to be used by ET 😊)
- Implies less transmit antenna gain by factor of $(32/1.42)^2 = 500$ 😞
- Solutions include significantly increasing dish diameter(s) and/or assumed transmitter power.
- Dish surface accuracy, pointing requirements, and resulting dwell and scan times are also potentially problematic ...
